Time-of-Travel of Solute Data Collected by the Mississippi Department of Environmental Quality for Mississippi Streams

By J. Kerry Arthur

ABSTRACT

This report summarizes the time-of-travel of solutes information for Mississippi streams that is available in the files at the Mississippi Department of Environmental Quality, Office of Pollution Control. The time-of-travel information was tabulated for 112 miles of stream reaches in eight of the ten major drainage basins in the State. The data were collected during studies conducted from 1981 through 1998. Estimation of time-of-travel of solutes is important for environmental studies of streams and may be critical in the event of accidental or other spills of contaminants into a waterway.

INTRODUCTION

The U.S. Geological Survey (USGS) collaborated with the Mississippi Department of Environmental Quality, Office of Pollution Control (MDEQ-OPC), in a project to compile all the time-of-travel of solute information on Mississippi streams available at the USGS and the MDEQ-OPC. This report is the second of two reports to present the time-of-travel information. The first report presented the data located in the files of the USGS.

This report presents, in tabular form, all the available time-of-travel information for Mississippi streams located in the files of the MDEQ-OPC. The compilation of these data into a single document facilitates the use of the data.

The possibility of accidental or intentional (bio-terrorism) spills of contaminants into Mississippi streams is of concern to those using water from the rivers in the State. Estimating solute travel time in streams is important in the event of spills of contaminants and for pollution studies. A tabulation of all the time-of-travel information for Mississippi streams in the files of the MDEQ-OPC will be beneficial to the public and to local, State, and Federal agencies.

The time-of-travel information at MDEQ-OPC was collected from 1981 through 1998 along 112 miles of stream reaches in the State. The streams for which information is available represent eight of the ten major drainage basins (fig. 1). All the time-of-travel information presented in this report was collected by the MDEQ-OPC or by contracted representatives of MDEQ-OPC.

The time-of-travel data were collected as part of various MDEQ-OPC studies to determine the movement of a potential

contaminant through the reaches of a waterway. Most, if not all, the studies were conducted to determine solute travel time from lagoon outfalls to relatively short distances downstream to selected sampling sites. The studies used similar procedures to determine solute time-of-travel. The time-of-travel data were determined by injecting known amounts of fluorescent dye into streams at selected sites and measuring the travel time of the dye to downstream sampling points. Slug injections of Rhodamine WT fluorescent dye were used in all of the studies except in the September 1989 study on Sipsey Creek where the constant-injection method was used to input the Rhodamine WT dye into the stream. The dye concentrations in the water samples collected were measured using a fluorometer. The travel time of the dye was determined by using the time of collection of the water sample containing the peak concentration of dye. In some of the studies, the time-of-travel of the leading and trailing edges of the dye cloud was determined. The leading edge of the dye plume is the first detection of a dye concentration greater than background fluorescence. Most of the studies were made during periods with little or no surface runoff or during periods when the streams were at or near base flow conditions. Stream discharge measurements were made during most of the studies; discharge was estimated for most sites where measurements were not available. Latitude and longitude for the study sites was determined by using USGS 7 ½-minute quadrangle maps and information furnished by MDEQ-OPC.

PRESENTATION OF DATA

Time-of-travel of solute information was compiled from the individual study files and reports at the MDEQ-OPC. In instances where the information was in field form, the data were inspected and tabulated. Time-of-travel information was tabulated for the following drainage basins and stream groups in Mississippi (fig. 1).

- Tombigbee River Basin (fig. 2)
- Pascagoula River Basin (fig. 3)
- Pearl River Basin (fig. 4)
- Yazoo River Basin (fig. 5)
- Big Black River Basin (fig. 6)

- Independent Streams Basin (fig. 7)
- Tennessee River Basin (fig. 8)
- Lower Mississippi-Tennessee Streams Basin (fig. 9)

The stream reaches in each basin with time-of-travel of solute information are shown in figures 2-9. The drainage basin names are consistent with the names used by the MDEQ-OPC.

The time-of-travel of solute information for Mississippi streams is presented in table 1. The data tabulated for each stream consist of the following parameters:

- **Source and date of study**—Name, month, and year of study.
- **Reach**—Location of beginning and end of reach.
- **Reach number**—Numerical designation of reach.
- **County**—Name of county of reach.
- **Latitude**—Degrees, minutes, and seconds of latitude at beginning and end of reach.
- **Longitude**—Degrees, minutes, and seconds of longitude at beginning and end of reach.
- **Length of reach**—Length of reach in miles.
- **Solute time-of-travel, in hours**—Elapsed travel time of dye cloud from the beginning to the end of the reach.
 - **Lead edge**—Leading edge of dye cloud.
 - **Peak**—Peak concentration in dye cloud.
 - **Trail edge**—Trailing edge of dye cloud.
- **Solute rate of travel, in miles per hour**—Rate of travel time of dye cloud from the beginning to the end of the reach.
 - **Lead edge**—Leading edge of dye cloud.
 - **Peak**—Peak concentration in dye cloud.
- **Stream discharge, in cubic feet per second**.

The Pascagoula River Basin (fig. 3) has the greatest total miles (22.4) of river reaches with time-of-travel of solute information. The Tombigbee River Basin (fig. 2) has the second greatest total miles (20.5) of river reaches with time-of-travel of solute information. Tallahala Creek near Laurel has the greatest miles (17.7) of river reaches with data in the Pascagoula River Basin and the most miles of river reaches with information of all the rivers tabulated. Chico Creek near Houston has the greatest miles (7.70) of river reaches with data in the Tombigbee River Basin. The basin with the next greatest miles (18.6) of river reaches with time-of-travel information is the Yazoo River Basin (fig. 5). The Yalobusha River

near Grenada has the greatest miles (7.78) of river reaches with data in the Yazoo River Basin. Of the remaining basins with time-of-travel data, the Tennessee River Basin (fig. 8) has the least miles (3.70) of time-of-travel information all of which are on Indian Creek at Iuka. In the Big Black Basin, time-of-travel information was collected only on Bear Creek near Canton. No time-of-travel data are available on stream reaches in the coastal streams basin and in the Mississippi River Basin.

The Bogue Chitto River near Brookhaven in the Independent Streams Basin has the second greatest miles (12.1) of river reaches with time-of-travel of solute information. Bear Creek near Canton in the Big Black River Basin has the next greatest miles (9.00 miles) of river reaches with time-of-travel information. The Yalobusha River near Grenada in the Yazoo River Basin has the third greatest miles (7.78) of river reaches with data. Sowashee Creek at Savannah Grove has all the river reach mileage (4.71) with time-of-travel information in the Pascagoula River Basin. Data were collected on Sowashee Creek for three streamflow rates. Data were collected on Sipsey Creek near Sebastopol for two streamflow rates. For all other stream studies, time-of-travel information for each stream reach was collected for one streamflow rate.
